HOMEWORK 3

Collaborators*: Laura Thomas

*Listed in no particular order. And anyone I discussed at least part of one problem with is considered a collaborator.

1: From A&F: 2.2.4.

Let α be a real number. Show that the set of all values of the multivalued function $\log(z^\alpha)$ is not necessarily the same as that of $\alpha \log z$.

Solution:

Let's begin by looking at a precise counter example. Note when we use the $\log(z)$ we are taking the principal branch where $\theta \in [-\pi, \pi)$. Let $\alpha = 3$ and $z = i = e^{i\frac{\pi}{2}}$, then

$$\begin{aligned}\alpha \log z &= 3 \log \left(e^{i\frac{\pi}{2}} \right) \\ &= \frac{3i\pi}{2}.\end{aligned}$$

Additionally,

$$\begin{aligned}\log z^\alpha &= \log \left((e^{i\frac{\pi}{2}})^3 \right) \\ &= \log \left(e^{i\frac{3\pi}{2}} \right).\end{aligned}$$

Since $\frac{3\pi}{2}$ is not in our admissible range for θ we need to adjust it. Now

$$e^{i\frac{3\pi}{2}} = e^{i(\frac{3\pi}{2} + 2\pi k)} = e^{-i\frac{\pi}{2}},$$

where $k \in \mathbb{Z}$ and then taken specifically to be $k = -1$. Now plugging this back into our calculation of our specific $\log z^\alpha$ we see

$$\log z^\alpha = \log \left(e^{i\frac{3\pi}{2}} \right) = \log \left(e^{-i\frac{\pi}{2}} \right) = -i\frac{\pi}{2} \neq \frac{3i\pi}{2} = \alpha \log z$$

Therefore, the values of $\log(z^\alpha)$ are not necessarily the same as that of $\alpha \log z$. \square

2: Describe the Riemann surface on which the multi-valued function $w(z)$, defined by $w^2 = \prod_{j=1}^{n=3} (z - a_j)$ is single-valued. What happens for $n = 4, 5$? For $n > 5$? You may assume that all the a_j are distinct.

Solution:

Before describing the Riemann Surfaces for these cases, I want to establish how I am interpreting $()^{\frac{1}{2}}$ in the context of this problem. I am choosing the principal branch for the function $()^{\frac{1}{2}}$ such that

$$((z - a_j)(z - a_i))^{\frac{1}{2}} = (z - a_j)^{\frac{1}{2}}(z - a_i)^{\frac{1}{2}}.$$

The branch cut will once again limit the values of θ to the interval $[-\pi, \pi)$. Any time we have multiple branch points we need first inspect if any of the branch cuts overlap. We have to be very careful about the behavior of overlapping branch cuts. For

simplicity, we are taking all branch cuts to be from the branch point a_j going to the left (such that it is the complex number where the $\Re z < \Re a_j$ that is the branch cut which binds $\theta \in [-\pi, \pi)$. Additionally we add a bit of notation to aid in our discussion of overlapping branch cuts. We write $f(z) = \prod_{j=1}^{n=3} (z - a_j)$ which can be broken down into components

$$\begin{aligned} f(z) &= \left(\prod_{j=1}^n (z - a_j) \right)^{\frac{1}{2}} \\ &= \prod_{j=1}^n (z - a_j)^{\frac{1}{2}} \\ &= (z - a_1)^{\frac{1}{2}} (z - a_2)^{\frac{1}{2}} \dots (z - a_n)^{\frac{1}{2}} \\ &= f_1(z) f_2(z) \dots f_n(z), \end{aligned}$$

where the second and third lines are equal due to our choice of branch cut as stated at the start of the problem. Now we need to draw a few pictures and go through a few cases. Let's begin with the case where $n = 3$ where we have $f(z) = f_1(z) f_2(z) f_3(z)$. Now looking at Figure 1, I have drawn a feasible Riemann surface step by step. In step 1) I represent each of the branch cuts starting at the branch points for each f_1 , f_2 , and f_3 . Notice that a_2 and a_3 happen to be such that $\Re a_2 = \Re a_3$ therefore their branch cuts overlap from $(-\infty, a_2]$. Now we investigate the behavior of overlapping branch cuts. The branch cut for a_2 corresponds to where the sign of f_2 flips, similarly for f_3 's sign flipping. Notice if the branch cuts overlap, then both f_2 and f_3 's signs will flip from $+$ to $-$ at the same time. Notice

$$f_2 f_3 = (-f_2)(-f_3)$$

therefore overlapping branch cuts actually can cancel one another out. However, also observe (as a preview to the example I give when $n = 5$ in Figure 2)

$$f_1 f_2 f_3 \neq (-f_1)(-f_2)(-f_3) = -f_1 f_2 f_3.$$

Therefore, we have that an even number of overlapping branch cuts cancel one another out, but an odd number of overlapping branch cuts is indeed still a branch cut. I will proceed to carefully describe the $n = 3$ case, however these principles can easily be applied and understood as one inspects the drawings for the $n = 4$ and $n = 5$ cases. Now returning to our specific scenario drawn for $n = 3$, applying what we have established for overlapping branch cuts, the a_3 branch cut cancels out the whole a_2 branch cut and only leaves the section of the a_3 branch cut from a_3 to a_2 (as depicted in part 2 of Figure 1). Additionally we have a branch cut from a_1 to $-\infty$ which evidently is the same as ∞ in the complex plane (Riemann Sphere).

Now steps, 3-5 of Figure 1, proceed through the process of "stretching" these branch cuts apart in two copies of the complex sphere and lining them up appropriately with one another to form a Riemann Surface of a donut shape. The number of connections between these two copies of the complex sphere depends on the number of branch cuts that remain in the complex domain after we have worked out the overlapping cases. In Figure 2 I have depicted the scenario when $n = 5$ and a_1, a_2, a_3, a_4, a_5 happen to be dispersed in the complex plane such that we are left with 3 branch cuts. Therefore there are 3 places to line up the stretched branch cuts in the complex sphere. The resulting Riemann Surface in such a scenario is the depicted double torus. These are the types

of Riemann Surfaces which result from a function such as $f(z) = \left(\prod_{j=1}^n (z - a_j)\right)^{\frac{1}{2}}$. \square

3: From A&F: 2.2.5a.

Derive the following formulae:

a)

$$\coth^{-1}(z) = \frac{1}{2} \log \frac{z+1}{z-1}$$

Solution:

We begin with solving for w in $z = \coth w$ with $w, z \in \mathbb{C}$.

$$\begin{aligned} z = \coth w &= \frac{\cosh w}{\sinh w} = \frac{\frac{e^w + e^{-w}}{2}}{\frac{e^w - e^{-w}}{2}} = \frac{e^w + e^{-w}}{e^w - e^{-w}} \\ &= \frac{e^w}{e^w} \frac{e^w + e^{-w}}{e^w - e^{-w}} = \frac{e^{2w} + 1}{e^{2w} - 1} \end{aligned}$$

Now let's proceed by multiplying both sides by the denominator

$$\begin{aligned} z(e^{2w} - 1) &= e^{2w} + 1 \\ ze^{2w} - z &= e^{2w} + 1 \\ ze^{2w} - e^{2w} &= z + 1 \\ e^{2w}(z - 1) &= z + 1 \\ e^{2w} &= \frac{z+1}{z-1} \\ \log(e^{2w}) &= \log\left(\frac{z+1}{z-1}\right) + 2i\pi k, \quad k \in \mathbb{Z} \\ 2w &= \log\left(\frac{z+1}{z-1}\right) + 2i\pi k, \quad k \in \mathbb{Z} \\ w &= \frac{1}{2} \log\left(\frac{z+1}{z-1}\right) + i\pi k, \quad k \in \mathbb{Z} \end{aligned}$$

This is to show

$$\coth^{-1}(z) = \operatorname{arccot}(\coth w) = w = \frac{1}{2} \log\left(\frac{z+1}{z-1}\right) + i\pi k, \quad k \in \mathbb{Z}.$$

More directly we have

$$\coth^{-1}(z) = \frac{1}{2} \log\left(\frac{z+1}{z-1}\right).$$

as required. Where the final statement comes from choosing the principal branch of the log, meaning $\theta \in [-\pi, \pi)$. We also take $k = 0$. \square

While you're at it, also derive a formula for $\operatorname{arccot}(z)$ in terms of the logarithm.

Solution:

Let's begin by solving for w in this equation $z = \cot w$ with $w, z \in \mathbb{C}$.

$$\begin{aligned} z = \cot w &= \frac{\cos w}{\sin w} = \frac{\frac{e^{iw} + e^{-iw}}{2}}{\frac{e^{iw} - e^{-iw}}{2i}} = \frac{i(e^{iw} + e^{-iw})}{e^{iw} - e^{-iw}} \\ &= \frac{e^{iw}}{e^{iw}} \frac{i(e^{iw} + e^{-iw})}{e^{iw} - e^{-iw}} = \frac{i(e^{2iw} + 1)}{e^{2iw} - 1} \end{aligned}$$

Now let's proceed by multiplying both sides by the denominator

$$\begin{aligned} z(e^{2iw} - 1) &= i(e^{2iw} + 1) \\ ze^{2iw} - z &= ie^{2iw} + i \\ ze^{2iw} - z - ie^{2iw} - i &= 0 \\ e^{2iw}(z - i) &= z + i \\ e^{2iw} &= \frac{z + i}{z - i} \\ \log(e^{2iw}) &= \log\left(\frac{z + i}{z - i}\right) + 2i\pi k, \quad k \in \mathbb{Z} \\ 2iw &= \log\left(\frac{z + i}{z - i}\right) + 2i\pi k, \quad k \in \mathbb{Z} \\ w &= \frac{1}{2i} \log\left(\frac{z + i}{z - i}\right) + \pi k, \quad k \in \mathbb{Z} \end{aligned}$$

This is to show

$$\operatorname{arccot}(z) = \operatorname{arccot}(\cot w) = w = \frac{1}{2i} \log\left(\frac{z + i}{z - i}\right) + \pi k, \quad k \in \mathbb{Z}.$$

More directly we have

$$\operatorname{arccot}(z) = \frac{1}{2i} \log\left(\frac{z + i}{z - i}\right) + \pi k, \quad k \in \mathbb{Z}$$

as required. Where the final statement comes from choosing the principal branch of the log, meaning $\theta \in [-\pi, \pi)$. We also take $k = 0$. \square

4: Let

$$s(z) = z^{1/2} = \rho^{1/2} e^{i\theta/2}, \quad \theta \in [-\pi, \pi),$$

denote the principal branch of the square root. Show that the functions

$$f_1(z) = s(z^2 - 1), \quad f_2(z) = s(z - 1)s(z + 1),$$

are not equal as functions on \mathbb{C} — first produce plots and then use a mathematical argument. Determine the branch cut for $f_2(z)$ (Note: My cartoon of what the branch cut for f_1 looks like in lecture was not accurate). Find the relationship between $f_1(z)$ and $f_2(z)$.

Solution:

Let's consider the potential branch point for f_1 at $z = 1$.

$$\begin{aligned}
 f_1(1 + \epsilon e^{i\theta}) &= s \left((1 + \epsilon e^{i\theta})^2 - 1 \right) \\
 &= \left((1 + \epsilon e^{i\theta})^2 - 1 \right)^{\frac{1}{2}} \\
 &= (1 + 2\epsilon e^{i\theta} + \epsilon^2 e^{2i\theta} - 1)^{\frac{1}{2}} \\
 &= (2\epsilon e^{i\theta} + \epsilon^2 e^{2i\theta})^{\frac{1}{2}} \\
 &\approx (2\epsilon e^{i\theta})^{\frac{1}{2}} \\
 &= (2\epsilon)^{\frac{1}{2}} e^{\frac{i\theta}{2}}, \quad \theta \in [-\pi, \pi).
 \end{aligned}$$

Now let's consider f_1 at $z = -1$

$$\begin{aligned}
 f_1(-1 + \epsilon e^{i\theta}) &= s \left((-1 + \epsilon e^{i\theta})^2 - 1 \right) \\
 &= \left((-1 + \epsilon e^{i\theta})^2 - 1 \right)^{\frac{1}{2}} \\
 &= (1 - 2\epsilon e^{i\theta} + \epsilon^2 e^{2i\theta} - 1)^{\frac{1}{2}} \\
 &= (-2\epsilon e^{i\theta} + \epsilon^2 e^{2i\theta})^{\frac{1}{2}} \\
 &\approx (-2\epsilon e^{i\theta})^{\frac{1}{2}} \\
 &= (-2\epsilon)^{\frac{1}{2}} e^{\frac{i\theta}{2}}, \quad \theta \in [-\pi, \pi) \\
 &= i(2\epsilon)^{\frac{1}{2}} e^{\frac{i\theta}{2}}, \quad \theta \in [-\pi, \pi)
 \end{aligned}$$

5: Consider the function

$$\psi(z) = \int_1^z \frac{dw}{(w^2 - 1)^{1/2}}, \quad z \notin (-\infty, 1),$$

where the path of integration is a straight line from 1 to z .

- Show that

$$\psi(z) = \log \varphi(z), \quad \varphi(z) = z + (z^2 - 1)^{1/2}, \quad z \notin (-\infty, 1),$$

for an appropriate choice of branch cut for $(z^2 - 1)^{1/2}$. Here $\log z$ denotes the principal branch.

Solution:

We will first show that $\log \varphi(z)$ is analytic. Showing that this function satisfies the Cauchy-Riemann equations or showing the formal definition of the derivative in terms of the limit is difficult. Rather, we will show $\log \varphi(z)$ is composed of analytic functions, given the correct choices of branches, where necessary. **TODO...**

Now we will show that $\log \varphi(z)$ is indeed the anti-derivative of what we have in the integrand. To show that $\log \varphi(z)$ is the anti-derivative of the integrand we begin

by taking the derivative of $\log \varphi(z)$.

$$\begin{aligned}\frac{d}{dz} \log(z + (z^2 - 1)^{1/2}) &= \frac{1}{(z + (z^2 - 1)^{1/2})} \left(1 + \frac{1}{2} \frac{2z}{(z^2 - 1)^{1/2}} \right) \\ &= \frac{1}{(z + (z^2 - 1)^{1/2})} \left(\frac{(z^2 - 1)^{1/2}}{(z^2 - 1)^{1/2}} + \frac{z}{(z^2 - 1)^{1/2}} \right) \\ &= \frac{1}{(z + (z^2 - 1)^{1/2})} \left(\frac{(z^2 - 1)^{1/2} + z}{(z^2 - 1)^{1/2}} \right) \\ &= \frac{1}{(z^2 - 1)^{1/2}}\end{aligned}$$

Which is the same as our term in the integrand. Now in this scenario we choose the branch cut for $(z^2 - 1)^{1/2}$ such that $(z^2 - 1)^{1/2} = (z + 1)^{1/2}(z - 1)^{1/2}$. That is the principal branch cut with $\theta \in [-\pi, \pi)$ and $k = 0$.

- Find an expression for

$$\gamma(z) = \int_{-1}^z \frac{dw}{(w^2 - 1)^{1/2}}, \quad z \notin (-1, \infty),$$

in terms of $\varphi(z)$ and the principal branch of the logarithm. Again, the path of integration is a straight line.

Solution:

- 6:** Show that φ , from the previous problem, maps $\mathbb{C} \setminus [-1, 1]$ onto the exterior of the unit disk, $\{z \in \mathbb{C} : |z| > 1\}$. Furthermore

$$\frac{1}{2} (\varphi(z) + 1/\varphi(z)) = z, \quad \mathbb{C} \setminus [-1, 1].$$

Solution:

- 7:** (Sharpness of the Bernstein–Walsh inequality) The Bernstein–Walsh inequality states that if a polynomial p_n of degree n satisfies $\max_{-1 \leq x \leq 1} |p_n(x)| \leq 1$ then

$$|p_n(z)| \leq |\varphi(z)|^n, \quad z \in \mathbb{C} \setminus [-1, 1].$$

Show that

$$T_n(z) = \frac{1}{2} (\varphi(z)^n + \varphi(z)^{-n}), \quad z \in \mathbb{C} \setminus [-1, 1]$$

is a polynomial that satisfies

$$\begin{aligned}\max_{-1 \leq x \leq 1} |T_n(x)| &= 1, \\ \lim_{n \rightarrow \infty} |T_n(z)|^{1/n} &= |\varphi(z)|,\end{aligned}$$

for any fixed $z \in \mathbb{C} \setminus [-1, 1]$.

Solution:

Bonus problem:

b)

$$\operatorname{sech}^{-1}(z) = \log \left(\frac{1 + (1 - z^2)^{\frac{1}{2}}}{z} \right)$$

Solution:

We begin with solving for w in $z = \operatorname{sech} w$ with $w, z \in \mathbb{C}$.

$$\begin{aligned} z = \operatorname{sech} w &= \frac{1}{\cosh w} = \frac{1}{\frac{e^w + e^{-w}}{2}} = \frac{2}{e^w + e^{-w}} \\ &= \frac{e^w}{e^w} \frac{2}{e^w + e^{-w}} = \frac{2e^w}{e^{2w} + 1} \end{aligned}$$

Now let's proceed by multiplying both sides by the denominator

$$\begin{aligned} z(e^{2w} + 1) &= 2e^w \\ ze^{2w} + z &= 2e^w \\ ze^{2w} - 2e^w + z &= 0 \end{aligned}$$

We now use the quadratic formula to solve for e^w

$$\begin{aligned} e^w &= \frac{2 + (4 - 4z^2)^{\frac{1}{2}}}{2z} \\ e^w &= \frac{2 + 2(1 - z^2)^{\frac{1}{2}}}{2z} \\ \log e^w &= \log \left(\frac{1 + (1 - z^2)^{\frac{1}{2}}}{z} \right) + 2i\pi k, \quad k \in \mathbb{Z} \\ w &= \log \left(\frac{1 + (1 - z^2)^{\frac{1}{2}}}{z} \right) + 2i\pi k, \quad k \in \mathbb{Z} \end{aligned}$$

This is to show

$$\operatorname{sech}^{-1}(z) = \operatorname{sech}^{-1}(\operatorname{sech} w) = w = \log \left(\frac{1 + (1 - z^2)^{\frac{1}{2}}}{z} \right) + 2i\pi k, \quad k \in \mathbb{Z}.$$

More directly we have

$$\operatorname{sech}^{-1}(z) = \log \left(\frac{1 + (1 - z^2)^{\frac{1}{2}}}{z} \right) + 2i\pi k, \quad k \in \mathbb{Z}.$$

as required. Where the final statement comes from choosing the principal branch of the log, meaning $\theta \in [-\pi, \pi)$. We also take $k = 0$. \square
